AllisWell Enterprise

Manage every work request in your factory from one place

Breakdowns, maintenance, purchasing, quality and customer requests: who took them, how long they took and how they ended, in one system.

Company introduction · October 2026

The screens come from the real product running on sample data from a Turkish demo factory. Company, person and record names are examples.

WHERE WE START

This is how requests move in most factories today

The work gets done, but nothing is recorded. When something goes wrong, no one can find out later who was waiting for what, and since when.

Phone, WhatsApp, the corridor

A breakdown stays with whoever heard about it. There is no record.

No one knows who took it

The same job goes to two people, or to no one at all.

Time is not measured

No one knows how long the line waited or how many hours the repair took.

Complaints stay in an inbox

No one follows up the customer's e-mail, so the customer calls again.

Shift changes lose information

A problem reported by the night shift is forgotten by morning.

The result: "How many breakdowns did we have last month, how long did they take to fix on average, which machine stopped most?" There is no reliable answer. And what is not measured cannot be improved.

WHAT IS ALLISWELL ENTERPRISE?

Every request in one record, from opening to closing

AllisWell Enterprise is a request management system. It routes requests from inside and outside the company to the right unit, measures how long they take and records how they ended. It is the same app on the web, desktop, tablet and phone.

1

A request is opened

From the app, by e-mail, from a web form, or by itself when a system goes down.

2

It reaches the right unit

The service catalogue and rules send it to that unit's list.

3

The clock starts

Response and resolution times follow the factory's working calendar.

4

It is assigned to a person

The request lands as a task on that person's own work list.

5

It is resolved

Messages, internal notes, attachments and time spent stay on the request.

6

The requester confirms

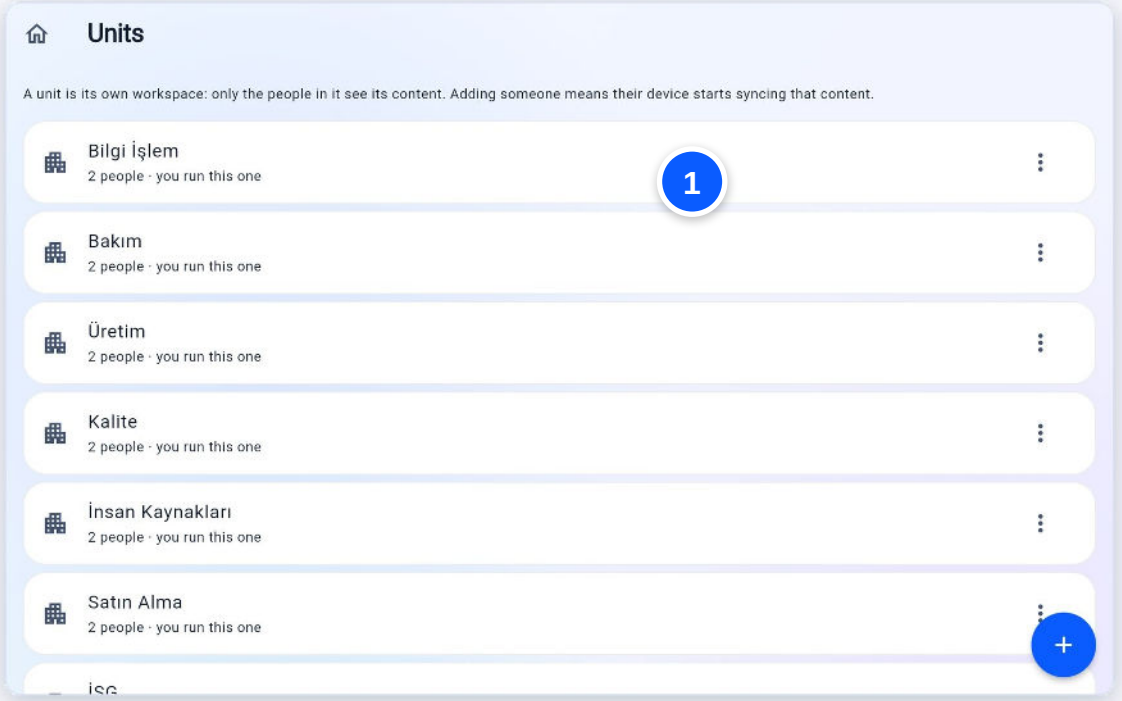

They say "Resolved" or reopen it, and rate their satisfaction.

The next pages show these steps in order: admin settings, request management, time tracking (SLA), people's work and requests from outside.

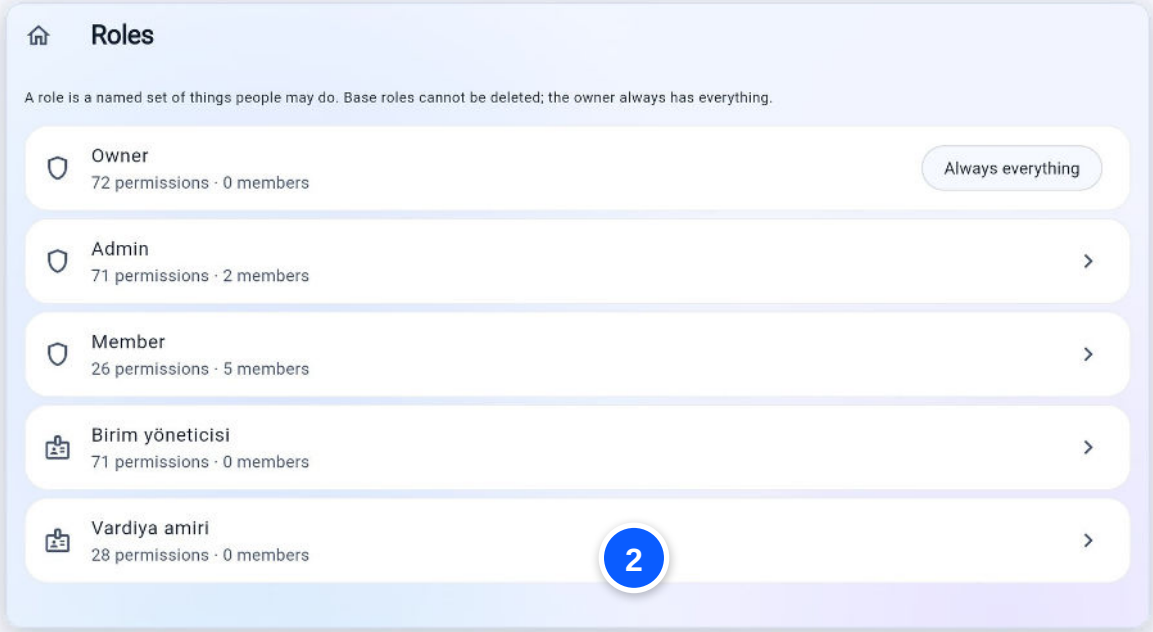

ADMIN INTERFACE

Your organisation chart, carried over one to one

Setup starts with units. Requests land in a unit, reports are grouped by unit, and permissions come from roles.

1 **Each unit** has its own request list, reports and members. One person can work in several units.

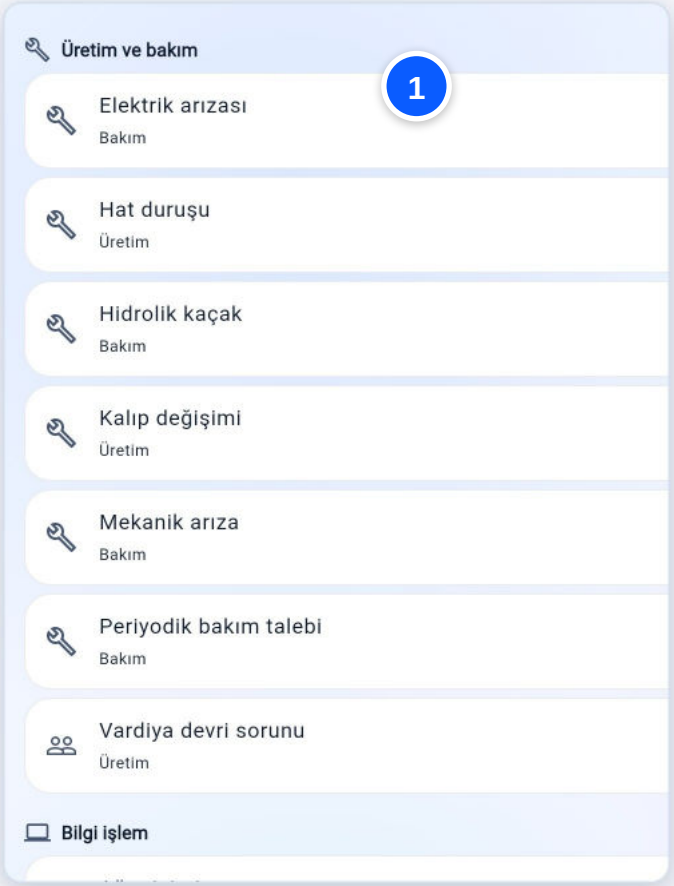

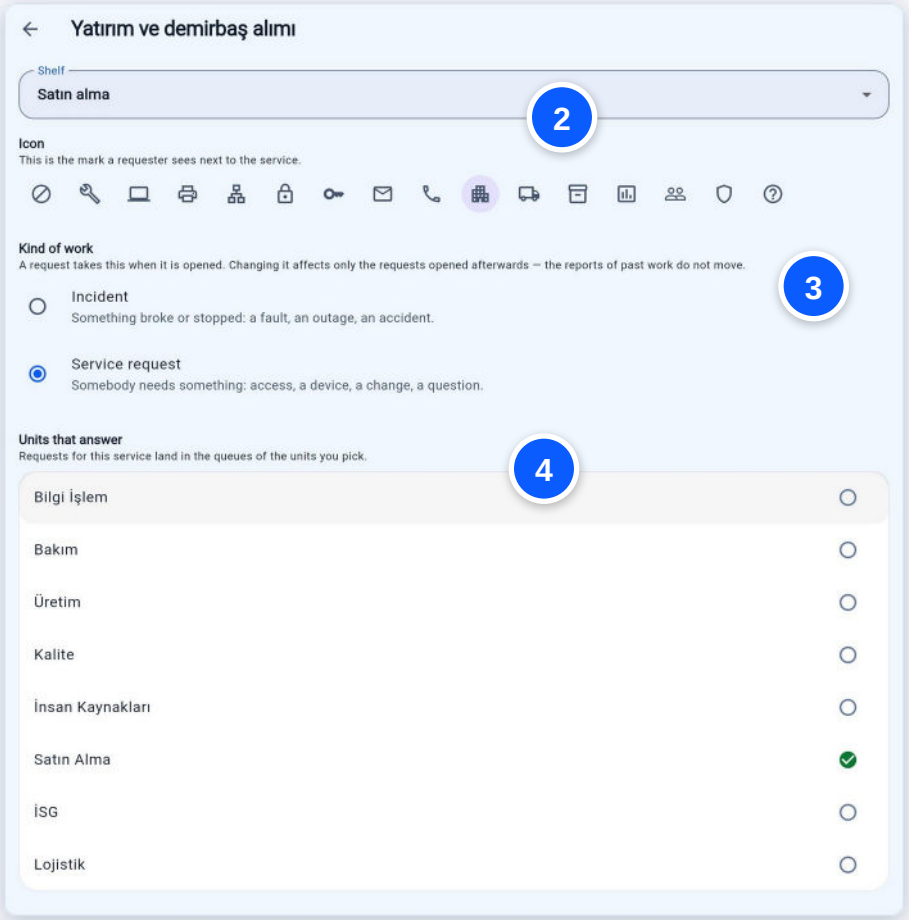

2 **Roles.** Besides owner, admin and member, you define custom roles such as "Shift supervisor". The role states who may assign, close or approve requests. No one from outside can sign up to your organisation's address.

ADMIN INTERFACE

Employees pick what they need from a menu

The service catalogue is the list a requester sees. For each service you set which unit receives it, what it asks and whether it needs approval.

1 **Shelves.** Services sit on shelves such as "Production and maintenance", "IT" and "Quality"; they can also be searched.

2 **Shelf and icon.** Requesters recognise the service by this mark.

3 **Breakdown or need?** A service is marked as an "incident" or a "service request"; reports measure the two separately.

4 **Owning unit and approval.** The request lands in the chosen unit. For services such as purchasing, a manager or named people sign off first.

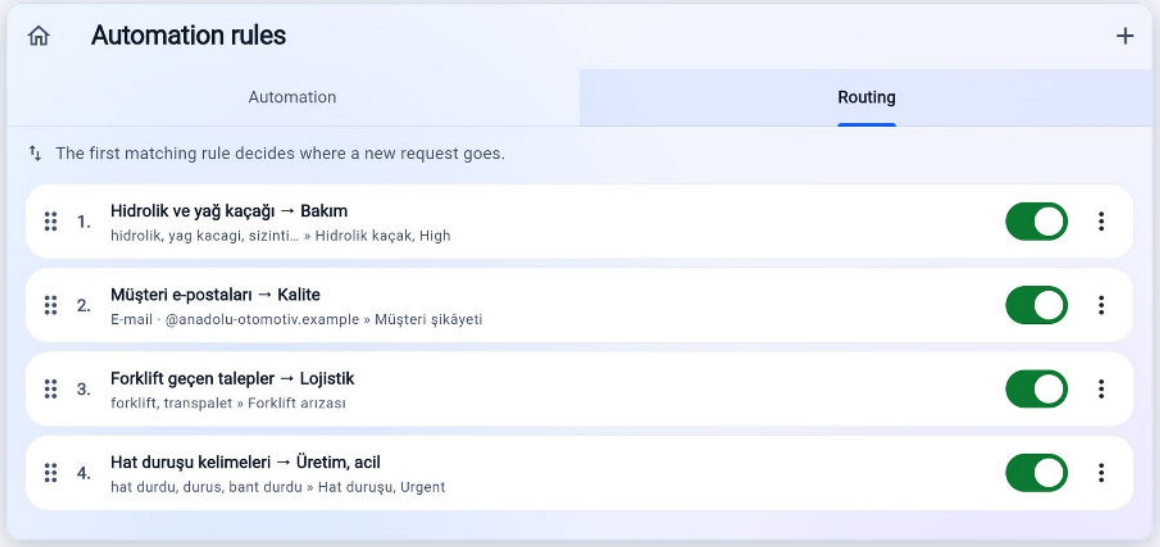

Services can ask their own questions ("Line number", "Estimated amount"). Every change to a form is a new version; older requests stay intact.

ADMIN INTERFACE

Rules send each request to the right place on their own

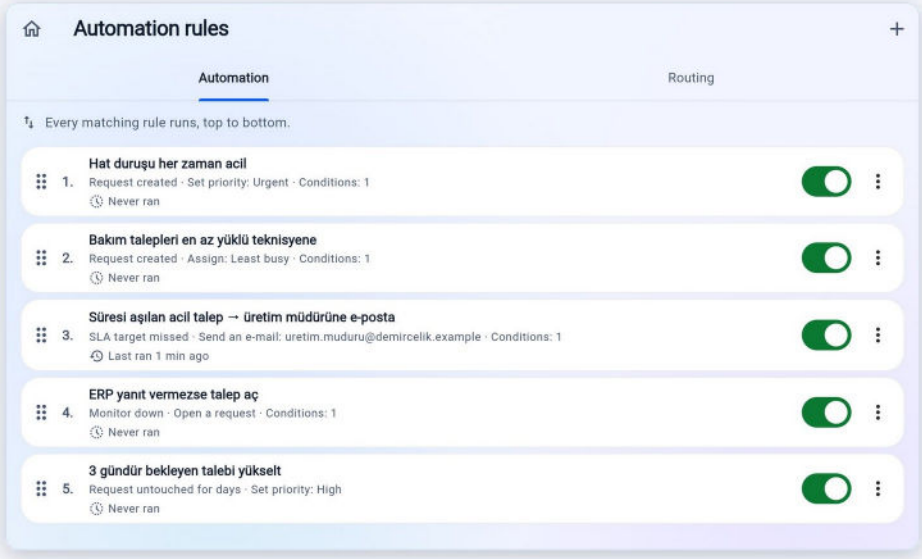

Routing: where does a new request go?

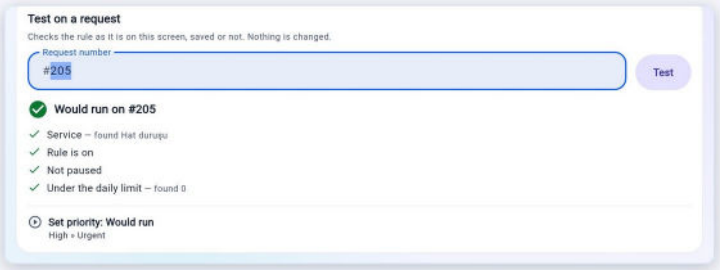

"If the subject mentions hydraulics or an oil leak, send it to Maintenance with high priority." The first matching rule decides.

Automation: what happens when something occurs?

"A line stoppage is always urgent." "E-mail the production manager when an urgent request misses its SLA." "Open a request if the ERP stops responding."

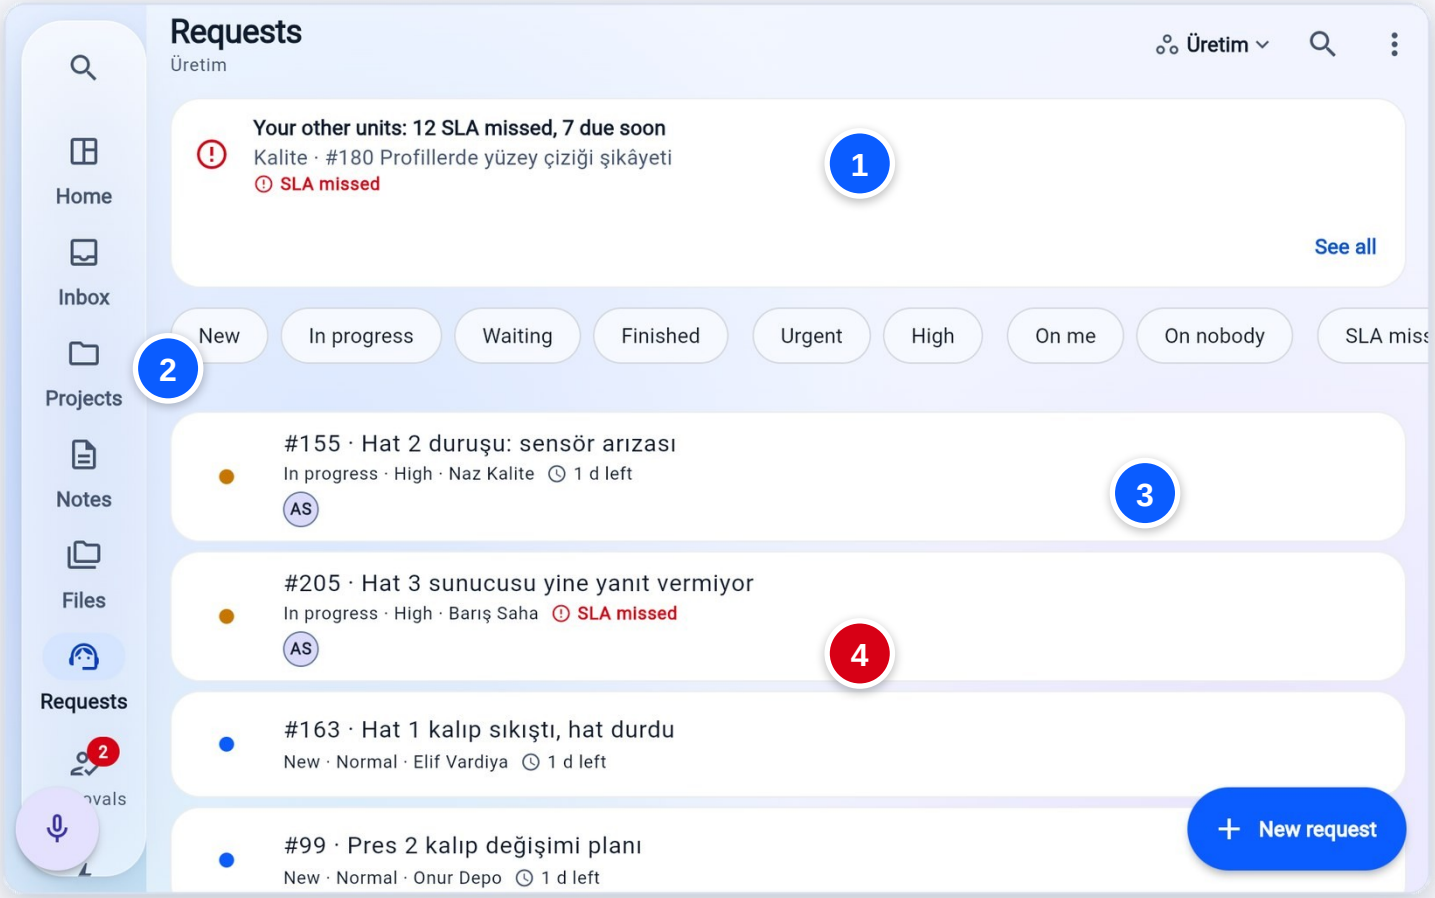

Try it before you save.
A rule is tried step by step on a real request number you type in: you see which condition matched and what the rule would do. Nothing changes. If a rule starts triggering itself over and over, the system stops it and says why.

REQUEST MANAGEMENT (ITSM)

Each unit works from its own request list

ITSM (request management) means answering "who asked for what and when, who took it, how long it took, how it ended" in a single record. Daily work runs on this list.

1. **Alerts from other units.** Someone who works in several units sees requests that missed their SLA in their other units at the top.

2. **Ready-made filters.** New, in progress, waiting, urgent, on me, on nobody, SLA missed, incidents…

3. **Each row is a request.** Number, subject, status, priority, requester, time left and the person handling it.

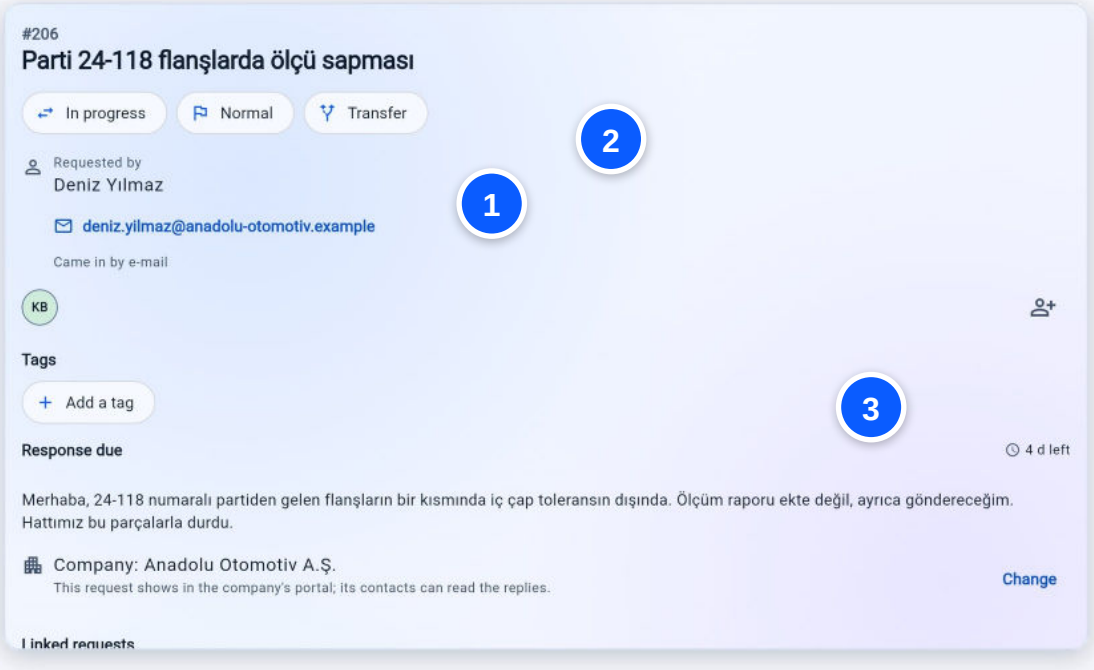

4. **A request that missed its SLA** is marked in red, so whoever opens the list sees it first.

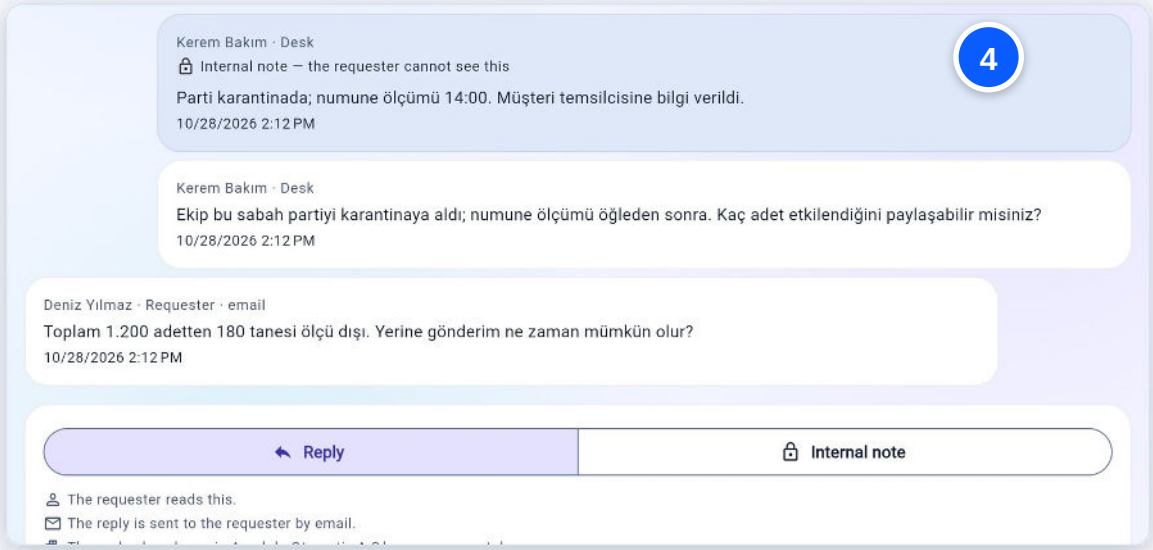

Status, priority or assignee can be changed for up to 100 requests at once.

REQUEST MANAGEMENT (ITSM)

The whole story of a request on one screen

Example: a dimensional deviation reported by e-mail by Anadolu Otomotiv. The request has landed in the Quality unit and the conversation is ongoing.

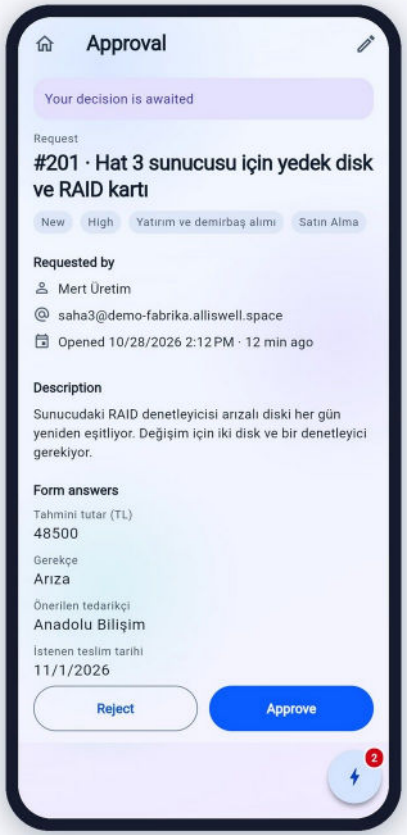

1. **Requester and source:** who wrote it, by e-mail or by form.
2. **Status, priority, transfer:** the request moves to another unit in one step.
3. **Time left and company:** time left to respond, linked customer.
4. **Reply and internal note are separate.** An internal note carries a lock icon; the requester never sees it on any screen.

Time spent is logged on the request. From the same screen you can open a change, a known error record or a knowledge base article.

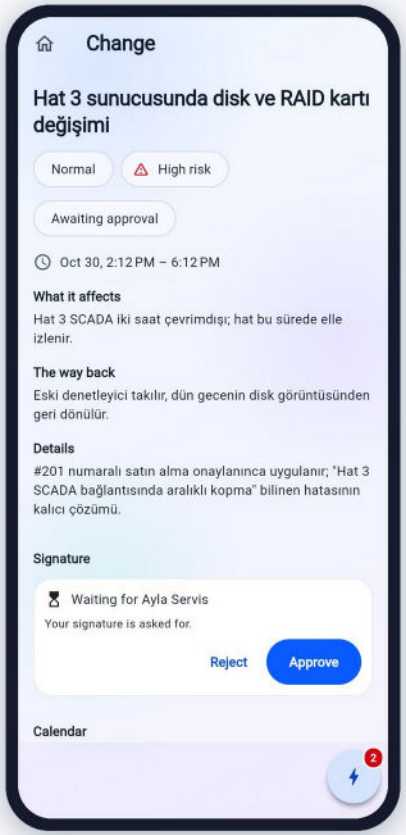

Work awaiting sign-off, planned changes, recurring breakdowns

All three come from the same story: the faulty RAID card in the Line 3 ("Hat 3") server.

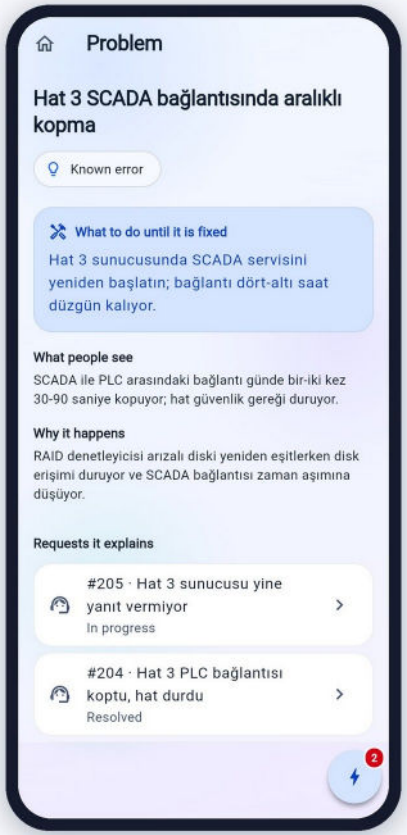

Approval

Purchase request #201: two disks and a RAID card. The approver sees the amount, reason, supplier and quote file on the phone, and approves or rejects with a written reason.

Planned change

The window, risk, impact and rollback plan for the disk swap. When the window clashes with the month-end stock count, the system warns; the change board must sign off.

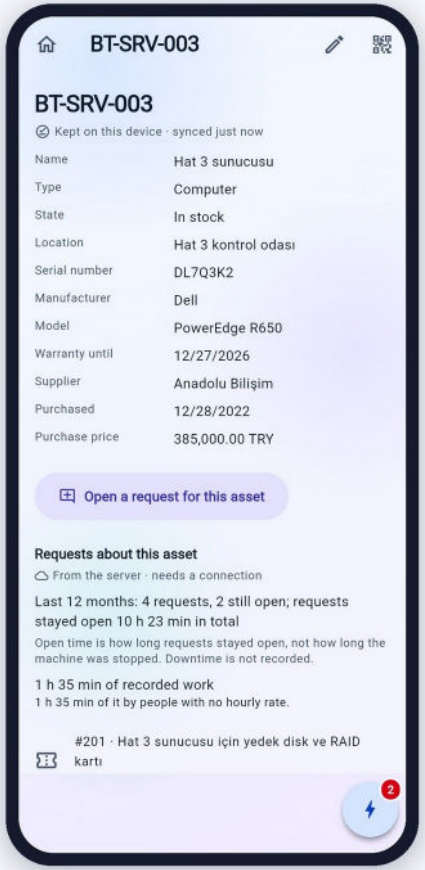

Known error

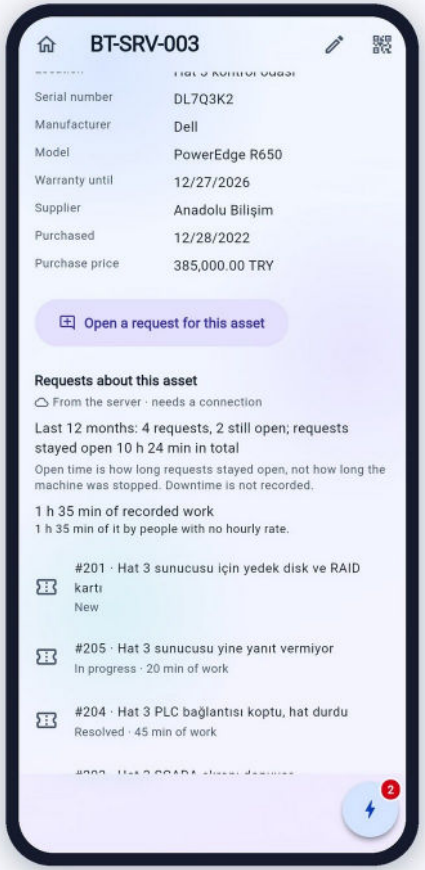

"Line 3 SCADA connection drops." Requests with the same cause sit in one record; what to do until it is fixed is written at the top.

REQUEST MANAGEMENT (ITSM)

Machines and known fixes are linked to requests too

Every machine has a record; every request opened for that machine is linked to it.

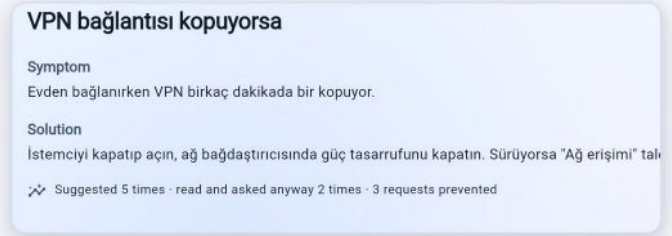

1. **Machine card.** Serial number, manufacturer, warranty end, supplier, purchase price. Scanning the label opens the card.

2. **Linked requests.** How many requests in the last 12 months, how many are still open, how much labour was spent.

3. **Planned changes.** Changes that affect the machine, and their windows, on the same card.

4. **Open a request.** The "Open a request for this asset" form opens with the machine selected.

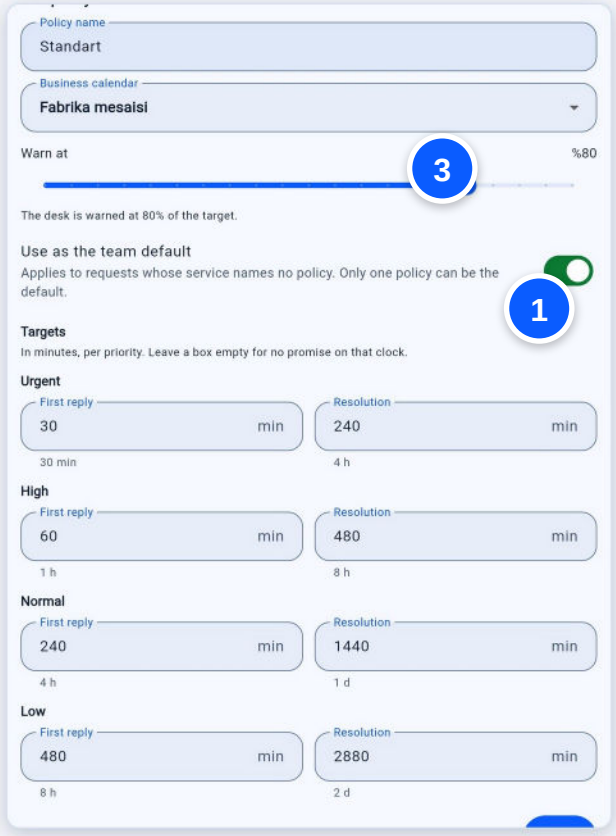

Knowledge base

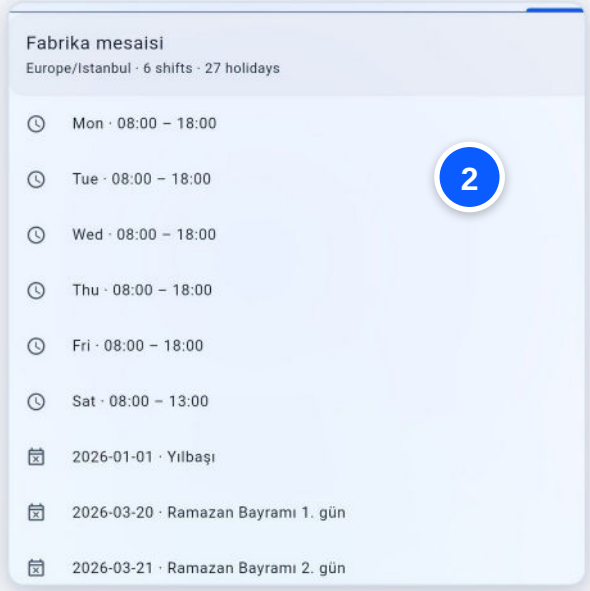

While a request is being written, the system suggests a matching solution. In the example, the "If the VPN connection drops" article was suggested 5 times and kept 3 requests from being opened.

SLA (SERVICE COMMITMENT)

A promise per request: minutes to respond, hours to resolve

An SLA is the promise of how soon a request gets a response and how soon it is resolved. The clock only runs during the factory's working hours.

1. **Two targets per priority.** Example: urgent requests get a response in 30 minutes and a fix in 4 hours; normal ones a response in 4 hours and a fix in 1 day.

2. **Factory working hours.** Weekdays 08:00–18:00, Saturday 08:00–13:00; public holidays are left out. A request opened at 03:00 starts counting at 08:00.

3. **Warning and escalation.** A warning at 80% of the time; once it is missed, the manager and the person on call are notified in the app, by e-mail and by phone notification.

4. **System monitors.** The ERP, barcode server and warehouse terminal are checked regularly; if one stops responding, a request opens by itself.

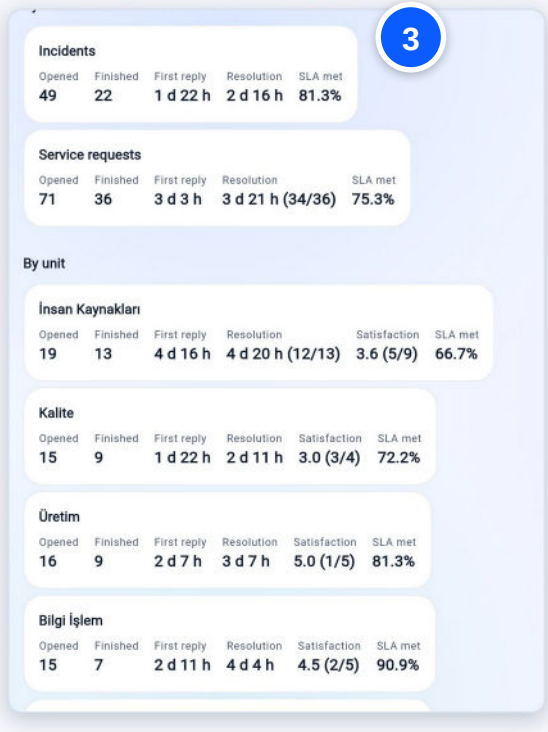

Only the unit's reply to the requester stops the clock. Entering a waiting reason (supplier, spare part, approval…) pauses it; no one can wind it back.

SLA (SERVICE COMMITMENT)

How much of the promise is kept, unit by unit

The figures are live; there is no separate report to prepare. Everyone sees the figures for their own units, managers see the whole factory.

1 **Promises kept** and requests per unit. The figures are sample data.

2 **Load by unit and service:** which service gets the most requests?

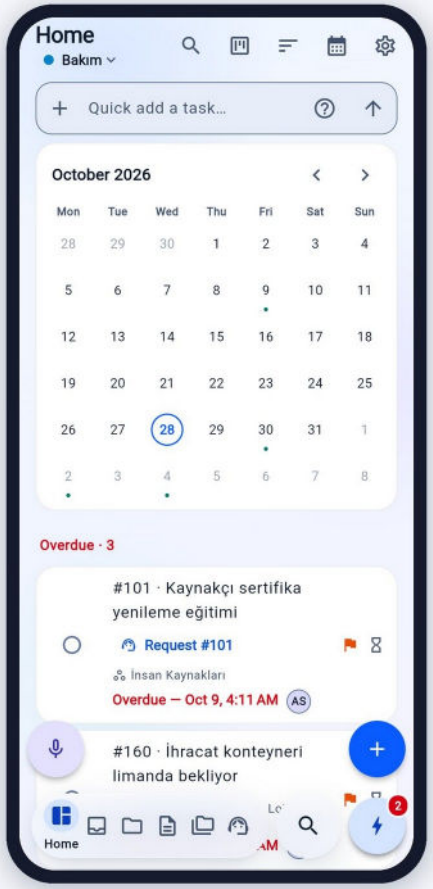

3 **Incidents and service requests apart.** Last 7, 30 or 90 days: opened, finished, first response and resolution time, SLA compliance, satisfaction.

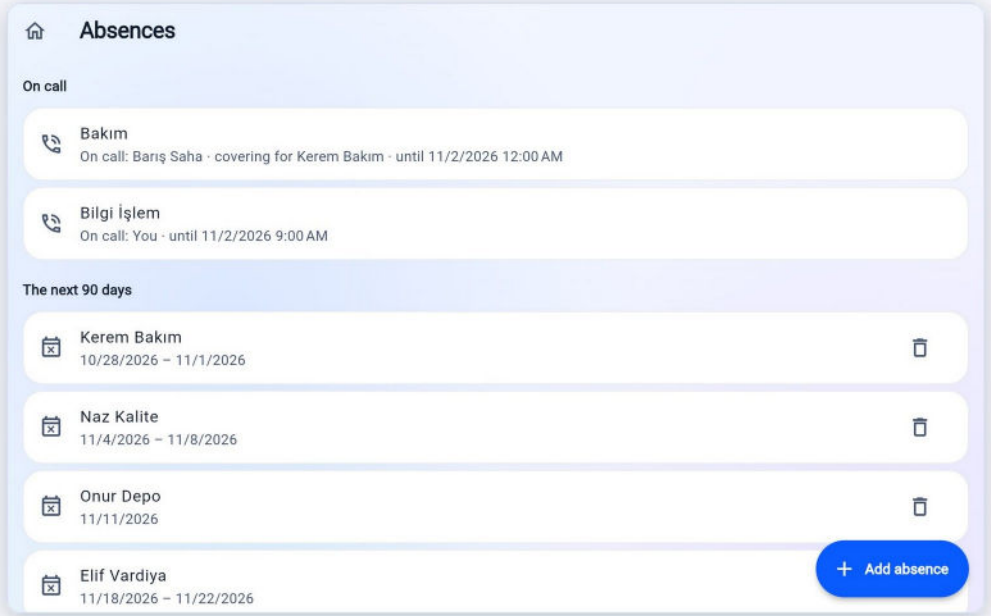

"How fast do we fix breakdowns?" The answer is here.

PEOPLE AND WORKLOAD

Everyone sees their own work list; managers see who has what

Being assigned to a request means a task on the person's Home page. Completing the task resolves the request.

Absence and on-call

In the Maintenance unit it was Kerem Bakım's turn on call; he is on leave, so Barış Saha is covering. Meanwhile no work is assigned to Kerem automatically.

1. **Own work list.** An assigned request appears on Home as "#41 · subject"; its due date comes from the request's SLA, overdue ones at the top.
2. **My units.** Someone who works in several units sees the open requests of all their units in one list, overdue ones first.
3. **Balanced assignment.** Work goes in turn or to the person with the least work. No automatic work goes to someone marked absent.
4. **On-call.** Each unit keeps an on-call rota; if the person on call is on leave, the next one takes over.

Request statuses and what the requester sees

The unit sees the detailed status; the requester sees a simple version of it. Internal details (such as whose approval is pending) never leave the company.

Waiting (a reason is required; the SLA clock stops while waiting)

Information from requester · Supplier · Spare part · Approval · Planned window

The requester sees "Waiting for your reply" when information is needed, "Waiting for approval" when a signature is pending, and "In progress" otherwise. As soon as they reply, the request goes back to "In progress" by itself and the clock runs again.

After resolution

The requester says "Yes, it is solved" or reopens it with "There is still a problem". A satisfaction survey follows when it closes. An unneeded request is "Cancelled"; cancelling and closing cannot be undone.

REQUESTS FROM OUTSIDE

Customers, dealers and suppliers send requests without an account

For factories that provide after-sales service: a request from outside goes into the same list, with the same time tracking, as an internal one.

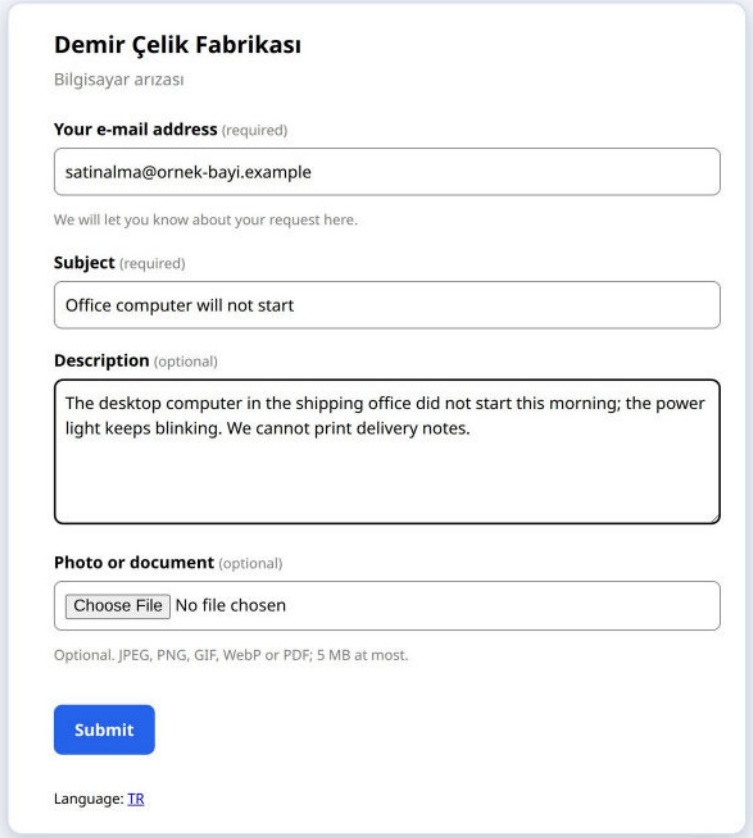

External request form
You share a time-limited link for a service. No account needed; photos or PDFs can be attached.

E-mail
E-mail to your support address becomes a request. Replies join the same request, even if the subject changes.

Company portal
People at contracted companies sign in with their own passwords and see all of their company's requests.

Phone
The unit opens the request on the caller's behalf; a tracking link goes to them by e-mail.

The link expires, or can be stopped at any time. Files from outside arrive marked "from outside"; virus scanning can be turned on at the server.

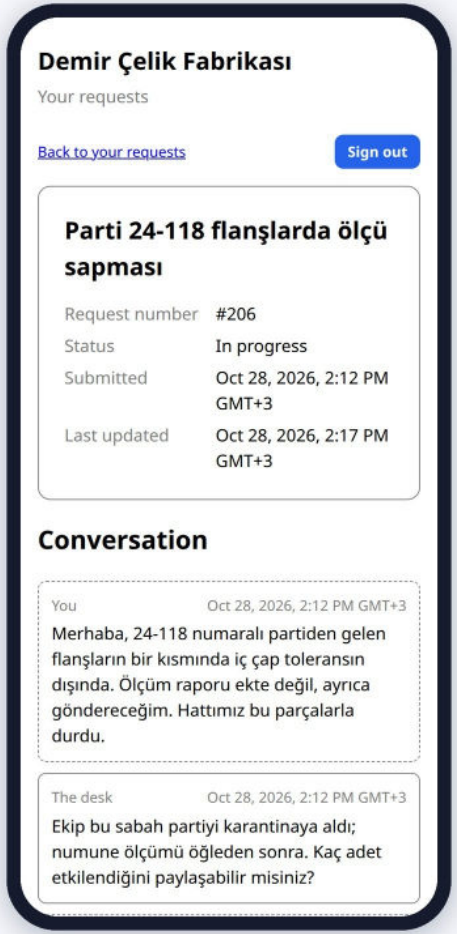

The form the customer sees

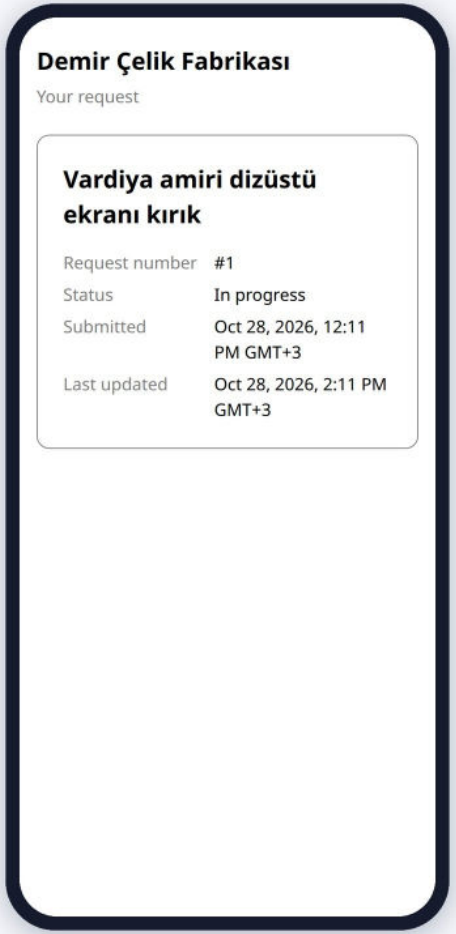

REQUESTS FROM OUTSIDE

Requesters see for themselves where their request stands

Customers no longer have to call and ask "what happened to my request?"

Company portal

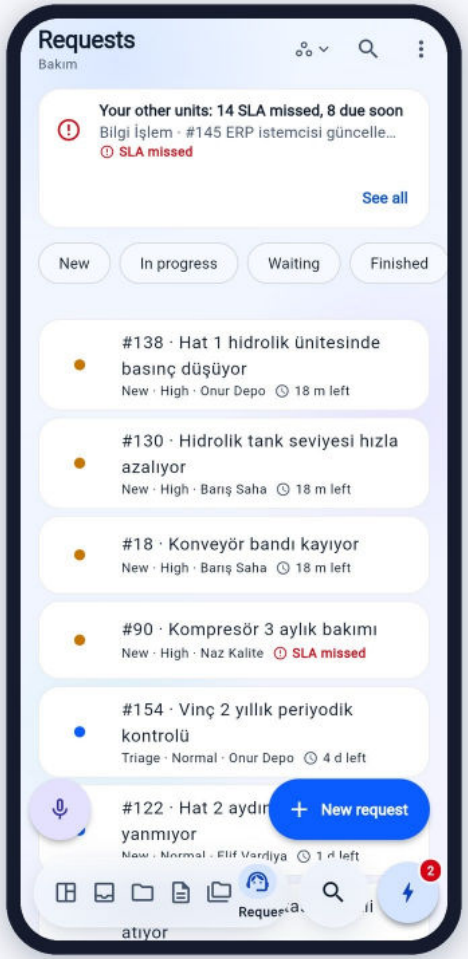

Tracking link

1. **Company portal.** Anadolu Otomotiv's people see all of the company's requests, reply, attach files and open new requests.
2. **The requester confirms closure.** They say "Yes, it is solved" or "There is still a problem"; a satisfaction survey follows when the request closes.
3. **Someone without an account** sees the status and the latest update from the tracking link they received.
4. **Internal information stays inside.** Internal notes, the unit's own conversation and who the approver is are never shown outside.
5. **Companies screen.** Add a company and invite its people; when someone leaves that company, their access is closed with one tap.

BUILT FOR FACTORIES

Works on the shop floor, with your rules and your data

Works without internet

The request list and requests open on the phone. A request written with no signal waits as a draft and is sent when the connection returns.

Data protection (KVKK): your data stays yours

Runs on your own server and database, or in the cloud at an address reserved for your organisation. All data can be exported as a single file; every change is written to an audit log.

Setup and migration by us

Our team does the installation. Service list, people and past requests are moved over from your current system (ServiceDesk Plus, Jira or Excel).

Start with one unit

Our suggestion: a trial of a few weeks with one unit such as Maintenance, then the other units. The package depends on your number of people and units.

Thank you

Write to us with your questions, or to arrange a live demo or a meeting.
